## **Chapter 8: Bootstrapping**

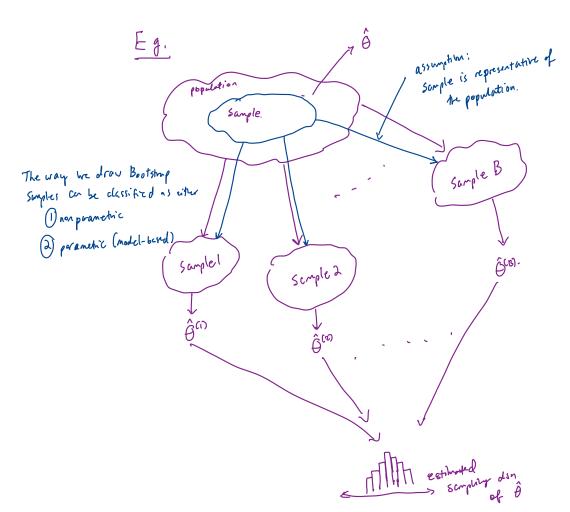

Typically in statistics, we use **theory** to derive the sampling distribution of a statistic. From the sampling distribution, we can obtain the variance, construct confidence intervals, perform hypothesis tests, and more.

#### Challenge:

What if the sampling distribution is impossible to obtain or asymptotic theory doesn't hold?

### Basic idea of bootstrapping:

- Use the data to estimate the sampling distribution of the statistic. Estimate the sampling distribution by creating a large # of detasets that we might have seen and compute the statistic on each of the datasets. "Pull yourself up by your bootstraps".

Goals of Boots trapping:

estimate bizs, se, and CIs when

- () There is doubt about whether distributional assumptions are met.
- 2) Tere is doubt about whether asymptotic results are valid
- 3) The theory to derive the dist of the first statistic is too hord.

# **1** Nonparametric Bootstrap

Let  $X_1, \ldots, X_n \sim F$  with pdf f(x). Recall, the cdf is defined as

$$F(x) = \int_{-\infty}^{\infty} f(t) dt = f(x \le x)$$

**Definition 1.1** The *empirical cdf* is a function which estimates the cdf using observed data,

 $\hat{F}(x) = F_{\widehat{m}}(x) = \text{ proportion of sample points that fall in } (\infty, x].$   $\stackrel{\text{to independs on the deta}}{\longrightarrow}$ In practice, this leads to the following function. Let  $X_{(1)} \leq X_{(2)} \leq \cdots \leq X_{(n)}$  be the <u>order</u> statistics of the sample. Then,

Sample in order 
$$F_n(x)= \left\{ egin{array}{ccc} 0 & x < X_{(1)} \\ rac{i}{n} & X_{(i)} \leq x < X_{(i+1)}; \quad i=1,\ldots,n-1 \\ 1 & x \geq X_{(n)} \end{array} 
ight.$$

$$F_n(\infty)$$
 is an estimator of  $F$  and as  $n \not \neg \infty$ ,  $F_n \rightarrow F$ .  
ecdf

Sample XNF, use X11-, Xn to compute Fn Theoretical:

Sample X\*NFn, use X1,..., X\* to compute F.\* Bootstrap:

**Example 1.1** Let x = 2, 2, 1, 1, 5, 4, 4, 3, 1, 2 be an observed sample. Find  $F_n(x)$ .

The idea behind the bootstrap is to sample many data sets from  $F_n(x)$ , which can be achieved by resampling from the data with replacement.

```
# observed data
x < -c(2, 2, 1, 1, 5, 4, 4, 3, 1, 2)
# create 10 bootstrap samples
x star <- matrix(NA, nrow = length(x), ncol = 10)</pre>
for(i in 1:10) {
  x star[, i] <- sample(x, length(x), replace = TRUE)</pre>
}
x star

## 1.1 Algorithm

**Goal:** estimate the sampling distribution of a statistic based on observed data  $x_1, \ldots, x_n$ . Let  $\theta$  be the parameter of interest and  $\hat{\theta}$  be an estimator of  $\theta$ . Then,

## **1.2 Properties of Estimators**

We can use the bootstrap to estimate different properties of estimators.

### 1.2.1 Standard Error

Recall  $se(\hat{\theta}) = \sqrt{Var(\hat{\theta})}$ . We can get a **bootstrap** estimate of the standard error:

### 1.2.2 Bias

Recall  $\operatorname{bias}(\hat{\theta}) = E[\hat{\theta} - \theta] = E[\hat{\theta}] - \theta.$ 

Example 1.2

We can get a **bootstrap** estimate of the bias:

Overall, we seek statistics with small se and small bias.

## **1.3** Sample Size and # Bootstrap Samples

 $n = ext{sample size} \quad \& \quad B = \# ext{ bootstap samples}$ 

If n is too small, or sample isn't representative of the population,

Guidelines for  ${\boldsymbol B}$  –

Best approach -

# Your Turn

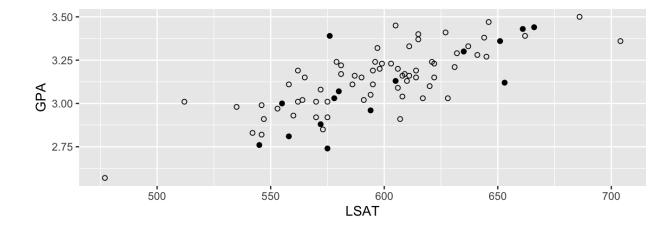

In this example, we explore bootstrapping in the rare case where we know the values for the entire population. If you have all the data from the population, you don't need to bootstrap (or really, inference). It is useful to learn about bootstrapping by comparing to the truth in this example.

In the package bootstrap is contained the average LSAT and GPA for admission to the population of 82 USA Law schools (an old data set – there are now over 200 law schools). This package also contains a random sample of size n = 15 from this dataset.

head(law) ## LSAT GPA ## 1 576 3.39 ## 2 635 3.30 ## 3 558 2.81 ## 4 578 3.03 ## 5 666 3.44 ## 6 580 3.07

library(bootstrap)

```
ggplot() +
geom_point(aes(LSAT, GPA), data = law) +
geom_point(aes(LSAT, GPA), data = law82, pch = 1)
```

We will estimate the correlation  $\theta = \rho(\text{LSAT}, \text{GPA})$  between these two variables and use a bootstrap to estimate the sample distribution of  $\hat{\theta}$ .

```
# sample correlation
cor(law$LSAT, law$GPA)
## [1] 0.7763745
# population correlation
cor(law82$LSAT, law82$GPA)
## [1] 0.7599979
# set up the bootstrap
B <- 200
n <- nrow(law)
r <- numeric(B) # storage
for(b in B) {
  ## Your Turn: Do the bootstrap!
}
```

- 1. Plot the sample distribution of  $\hat{\theta}$ . Add vertical lines for the true value  $\theta$  and the sample estimate  $\hat{\theta}$ .
- 2. Estimate  $sd(\hat{\theta})$ .
- 3. Estimate the bias of  $\hat{\theta}$
